structural protein of the extracellular matrix that is known to play an important role in wound healing. The aim of this study was to improve the abilities of collagen to facilitate wound healing. A porous collagen sponge was prepared from bovine tendon collagen through a freeze-drying process. The porous structure of the sponge was characterized by scanning electron microscopy. In vitro, the in vitro water-uptake rate, the in vitro degradation rate and the mechanical properties of the sponge were evaluated. In vivo, the abilities of the sponge to facilitate wound healing were evaluated by inducing wound in rats using porcine skin as a biologic barrier. The porous structure of the

sponge with a mean pore diameter of 0.82 ± 0.11 mm was clearly visualized under scanning electron microscopy. The water-uptake rate, the degradation rate and the mechanical properties of the sponge were 16.51 ± 0.63 g/g/hr, 11.01 ± 0.41%/hr, and 38.65 ± 0.89 MPa, respectively. The sponge was completely degraded and completely absorbed within 60 days. After transplantation to a wound site, the porous sponge was able to maintain its bulk until the wound site was completely healed. These results suggest that the porous collagen sponge is a biocompatible material that can be applied to wound sites and potentially used for other applications such as drug delivery

devices.[Transient Ischemic Attack. Role of perfusion and Diffusion weighted MRI in differential diagnosis]. Neuroimaging techniques are increasingly used in the management of acute stroke. We analyzed the role of perfusion (PWI) and diffusion (DWI) MRI in evaluating patients with ischemic stroke mimics, to identify the best technique to achieve an appropriate workup.
